General Data Prep

For general data preparation, please see conceptual steps below. See .rmd file for detailed code.

(i) Read Data

(ii) Impute Missing Values with PMM

Make data set of numeric variables hd.numericRaw

Make data set of factor variables hd.factorRaw

For each column with missing data, impute missing values with PMM

- 1. Imputation completed with our created function called imputeWithPMM()
- 2. Applies function to columns with missing data via dynamic dplyr logic
- 3. Note seeImputation() function to visualize the imputation from prior homework 4, not shown for simplicity in viewing
- ## [1] "LotFrontage" "MasVnrArea" "GarageYrBlt"
- ## [1] "For imputation results of LotFrontage, see OutputPMM/Imputation_With_PMM_LotFrontage.pdf"
- ## [1] "For imputation results of MasVnrArea, see OutputPMM/Imputation_With_PMM_MasVnrArea.pdf"
- ## [1] "For imputation results of GarageYrBlt, see OutputPMM/Imputation_With_PMM_GarageYrBlt.pdf"

(iii) Factor Level Collapsing

Overview: Create Other Bin for Columns over 4 Unique Values

- Applied to any factor column (previously character) with over 4 unique values
- Applies fct_lump() function to columns via dynamic dplyr logic
- ## [1] "Before cleaning, there are 14 factor columns with more than 4 unique values"
- ## [1] "After cleaning, there are 14 columns with more than 4 unique values (omitting NA's)"

(iv) Remove Outliers from Numeric Data

Overview: Using numeric data frame, remove *some* outliers from each column without dwindling the entire data set. See steps below to create data frame hd.CleanedNoOutliers.

- Please note that NOT all models use this data set with removed outliers.
 - Only models which are sensitive to outliers use this data frame without outliers.
 - For example, the linear model using this data frame.

Outlier removal steps below:

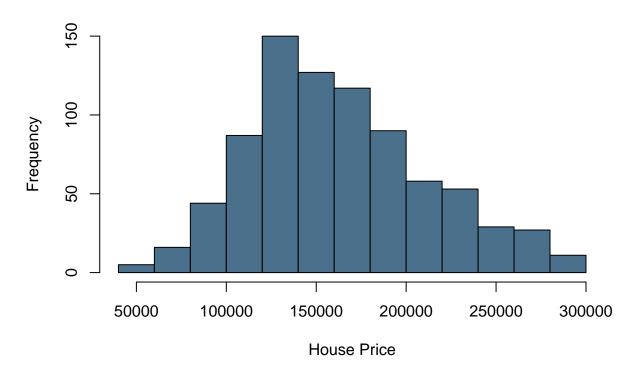

- Since there are so many outliers in each column, we are only going to remove some outliers
- If you count the number of outliers by column, the 75% of columns contain less than 50 outliers.
- However, some contain up to 200. Since remove ALL outliers would reduce the size of the data to less than 300 observations, we are removing up to 50 per numeric column.
- ## [1] "Of the columns with outliers, removed up to 75th percentile of num. outliers."
- ## [1] "See that the 75th percentile of columns with outliers contain 51.75 outliers"

Exploratory Data Analysis

Checking the distribution of Sale Price of houses

```
hist(hd.CleanedNoOutliers$SalePrice,
    col = 'skyblue4',
    main = 'Distribution of Sale Price of houses',
    xlab = 'House Price')
```

Distribution of Sale Price of houses

• After removing the desired outliers, we can see that the distribution of log(Sale Price) looks like a normal distribution with few outliers on the left tail.

Correlation between features in the dataset

```
ageofGarage
                                                                                   ageSinceRemodel 0.6
                                                                                              age 0.60.9
                                                                                     SalePrice -0.60.50.5
                                                                                    MiscVal
                                                                                PoolArea
                                                                          EncPorchSF
                                                                                              0 0.30.20.3

                                                                 0 0 0.20.1 0 0 0-0.1
                                                                                              0 - 0.20.20.2
```

• We can see that SalePrice has strong correlations with GarageArea, GarageCars, TotRmsAbvGrd, FullBath, GrLivArea, X1stFlrSF, TotalBsmtSF, OverallQual.

1 (a) - OLS Model

i.

Hold-out validation set

• Since, we have deleted some of the outlier values during data pre-processing, using 10% of the data as test and remaining 90% as train

```
idx <- sample(nrow(hd.CleanedNoOutliers), nrow(hd.CleanedNoOutliers)*0.1)
test <- hd.CleanedNoOutliers[idx,]
train <- hd.CleanedNoOutliers[-idx,]</pre>
```

Fit the OLS Model

Model 1:

- Linear model containing:
 - Independent variables: GarageArea + GarageCars + TotRmsAbvGrd + FullBath + GrLivArea + X1stFlrSF + TotalBsmtSF + OverallQual
 - Predicted variable: SalePrice

```
ols.mdl1 <- lm(log(SalePrice) ~ GarageArea + GarageCars + TotRmsAbvGrd
+ FullBath + GrLivArea + X1stFlrSF + TotalBsmtSF + OverallQual, data=train)
```

- For Model 1: Adjusted R-squared is 0.8138, AIC is -847.5004 and BIC is -801.5289 and RMSE is 171456.2.
- Still trying to improve the existing model.
- No multicollinearity detected.

Model 2:

- This model created is based on Principal Component Analysis.
 - Uses numeric data for Principal Component Analysis
 - Then appends the factor data to the data without NULL values
 - Finally, uses stepAIC() to best model data

Now we choose number of PC's that explain 75% of the variation

- Note this threshold is just a judgement call. No significance behind 75%
- ## [1] "There are 9 principal components that explain up to 75% of the variation in the data"

Fit the Model

- Linear model containing:
 - Principal components explaining 75% of variation in numeric data
 - Non-null factor data
 - Predicted variable: SalePrice
- Then use stepAIC() to identify which variables are actually important for model

```
# Fit data using PC's, non-null factors
fit.ols <- lm(log(SalePrice) ~ ., data = df.ols)

# Reduce to only important variables
ols.md12 <- stepAIC(fit.ols, direction="both")</pre>
```

• Reporting all the variables of the best model (Model 2):

Coefficient estimates:

```

RMSE:

[1] 0.09753504

- So, we can say that using PCA followed by stepAIC the OLS regression model is better as compared to the other OLS model built based on their adjusted R-squared value.
- There is also no multicollinearity found in the model as the VIF values are less than 10.

Model	Notes	Hyperparameters	RMSE	Rsquared
OLS	lm + 2-way interactions	N/A	0.097535	0.8932087

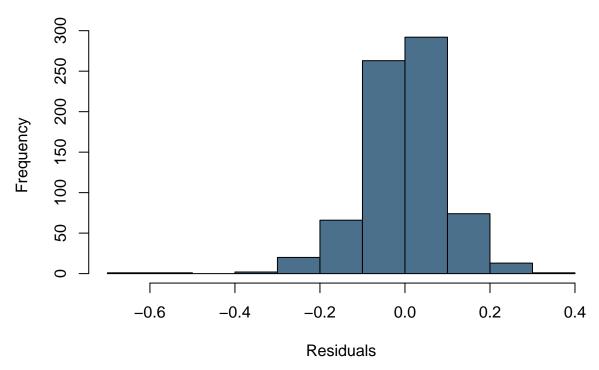

ii. Complete analysis of the residuals

A linear regression model is considered fit if the below assumptions are met:

- Residuals should follow normal distribution
- There should be no heteroscedasticity
- There should be no multicollinearity

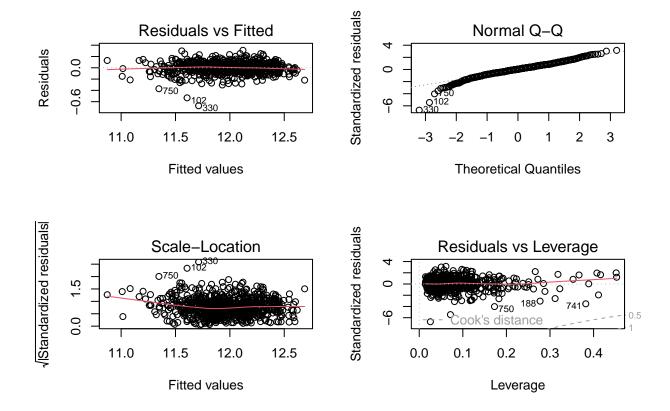

```
hist(ols.mdl2$residuals,
    col = 'skyblue4',
    main = 'Histogram of Residuals',
    xlab = 'Residuals')
```

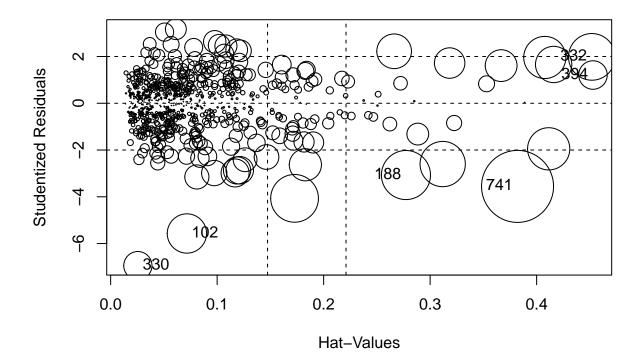

We can see that the residuals are normally distributed with a little longer left tail, maybe due to presence of outliers.

par(mfrow=c(2,2)) #combining multiple plots together
plot(ols.mdl2)

- From the Residuals vs Fitted plot, we can see there are points above and below the 0 line.
- There is also a pattern seen like a very slight curvature pattern towards the end which indicates that there maybe a systematic lack of fit.
- The mean of residuals is almost zero which implies there is no biasing involved.
- From the Normal Q-Q plot, we can see that most of the points are very close to the dotted line, indicating that the residuals follow a normal distribution, except some points which might be outliers which maybe affecting the regression line fit of data.
- Here the Scale-Location plot suggests that the red line is roughly horizontal across the plot and the spread of magnitude looks unequal, at some fitted values there are more residuals as compared to other like the ones in between 11.5 and and 12.5, indicating some heteroskedasticity.
- From the *Residuals vs Leverage* plot, we can see that there are no influential points close to the Cook's distance line in our regression model. We need to check influencePlot to see if we are missing any leverage.

influencePlot(ols.mdl2)

```
## StudRes Hat CookD

## 102 -5.569848 0.07159990 0.04243063

## 188 -3.069379 0.27728108 0.06611576

## 330 -6.944023 0.02555145 0.02189208

## 332 1.984052 0.45183522 0.05982835

## 394 1.207630 0.45289427 0.02234119

## 741 -3.555439 0.38206885 0.14230217
```

• We can now see some high influential points for the fitted values.

```
#ncv Test
ncvTest(ols.mdl2)
```

```
## Non-constant Variance Score Test
## Variance formula: ~ fitted.values
## Chisquare = 16.30918, Df = 1, p = 5.3803e-05
```

Since p-value is less than significance level (α) of 0.05, that means we reject the null hypothesis of constant error variance which indicates heteroscedasticity.

```

Generally, VIF values which are greater than 5 or 7 are the cause of multicollinearity which we do not see in our model.

Improving the current model:

- To improve our model, we need to remove some influential observations from our model and then fit the regression model to the data.
- We can re-build the model with new predictors.
- We can also perform variable transformation such as Box-Cox or use better evolved models like SVR, PCR etc., and see how it works.

1 (b) - PLS Model

Model Setup

- Using the whole data set after PMM imputation and factor level collapsing without omitting any outliers
- Using the predictors GarageArea, GarageCars, TotRmsAbvGrd, FullBath, GrLivArea, X1stFlrSF, TotalBsmtSF, OverallQual which has strong correlations with response variable SalePrice

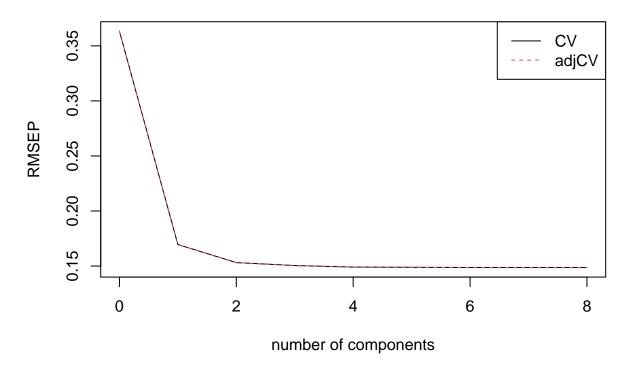

• Hyperparameter tuning to determine the number of PLS components with RMSE as the error metric

plot(RMSEP(pls.model),legendpos="topright")

log(SalePrice)

- From the table, we can see that if we use 6 PLS components only in our model, the RMSE drops to 0.1486 and after that even if we keep adding components the RMSE still is the same.
- Though we are eyeballing the CV component, but from the plot we can see that fitting 4 PLS components is enough because even if we are adding 2 more components there is not much difference in the CV component.
- Using the final model with four PLS components to make predictions

Fit the Model

- From the above plot, we can see that by using only four PLS components we can describe about 80% of the variation in the response variable.
- Metric Calculations:

Model	Notes	Hyperparameters	RMSE	Rsquared
PLS	pls	ncomp = 4	0.1474771	0.0218368

- If we now compare between our preferred OLS model and PLS model on basis of RMSE values, we can see that PLS model's efficiency is much higher.
- RMSE for chosen OLS model was ols.mdl2.rsme whereas for PLS model is 0.1475.
- But we see that the adjusted R-squared value for PLS model has significantly reduced to about 2%.
- We know that adjusted R-squared identifies the percentage of variance in the response that is explained by the predictors which PCA handles in a better way as PCA finds the composite variables of predictors that maximally explain the variability of the data, whereas PLS finds the composite variables of predictors that are most predictive of the response variable. So maybe that's why we have a less adjusted R-squared whereas a better RMSE value.

1 (c) - LASSO Model

Model Setup

- We first setup our cross-validation strategy
- Then create a dataframe with PMM imputed values, and only whole columns without NA. Does not omit outliers
- Then we train the model using glmnet which actually fits the elastic net

Fit the Model

• The variables with non-zero coefficients of the final model:

```
lasso.coeff <- drop(coef(fit.lasso$finalModel, fit.lasso$bestTune$lambda))
lasso.coeff[lasso.coeff != 0]</pre>
```

1 (d) - Model Variants

1 (d, i) - PCR Model

Model Setup

- Uses numeric data for Principal Component Analysis
 - Data includes outliers
 - Chose number of PC's that explain 75% of the variation. This is just a general judgement call to keep the number of principal components low.
- \bullet Then appends the factor columns without NULL values and SalePrice to the data
- Finally, uses stepAIC() to best model data
- See interpretation at end

[1] "There are 12 principal components that explain up to 75% of the variation in the data"

Join on the factor data and SalePrice

```
df.pcr <- cbind(SalePrice = hd.numericClean$SalePrice, chosenPCs, hd.factorClean)</pre>
```

Fit the Model

- Linear model containing:
 - Principal components explaining 75% of variation in numeric data
 - Non-null factor data
 - Predicted variable: log(SalePrice)
- Then use stepAIC() to identify which variables are actually important for model

```
# Fit data using PC's, non-null factors
fit.pcr <- lm(log(SalePrice) ~ ., data = df.pcr)

# Reduce to only important variables
fit.pcrReduced <- stepAIC(fit.pcr, direction="both")</pre>
```

Model	Notes	Hyperparameters	RMSE	Rsquared
PCR	lm, prcomp, and stepAIC	N/A	0.1011049	0.9179771

View and Interpret Results

Please note all interpretations below are approximate, given the stepAIC() uses stochastic modeling.

Model performance evaluation:

- See that around 28 of the variables cannot be explained by random chance, with a probability of 90% or more (see significance codes above)
- Standard errors range from \pm 1-5%, with average around 2%. Larger values may indicate higher uncertainty of the estimated coefficients.
- This model explains around 92% of the variation in the log(SalePrice). See Adjusted R-Squared for reference.
- Note this model may exhibit selection bias, since the data excludes factor data with null values in the variable.
- This model would likely doe well for prediction of log(SalePrice), given the small range of standard errors, high adjusted R squared, and number of significant variables. This model would obviously not do well for inference, given we are using principal components that mask the numeric data.

Practical significance evaluation:

- The principal components contribute positively about 20% of the sale price of the home
- Residential Medium Density (MSZoningRM) reduces the home price by around 12%, with a standard error of around 2%.
- If the exterior quality is below average (ExterQualBelowAvg), it reduces the home price by around 12%, with a standard error of around 5%.
- If the functionality of the home has 2 major deductions (FunctionalMaj2), it reduces the home price by around 20%, with a standard error of around 6%. While having typical functionality (FunctionalTyp) increases the home sale price by nearly 10%, with a standard error of 3%.
- See other coefficients of the data for other variables.

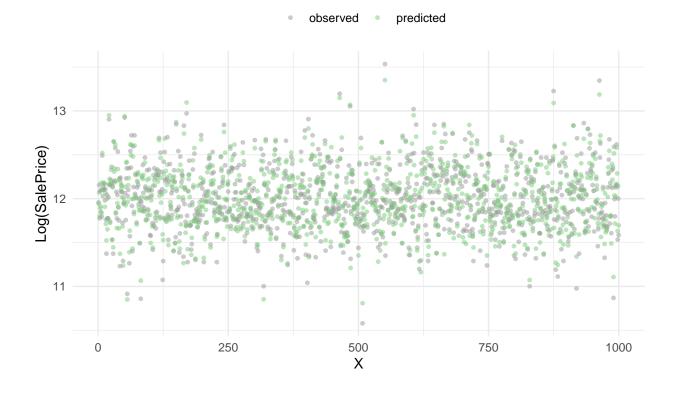

View Predicted vs. Actuals

Note that the Function predictedVsObserved() created to compare predicted vs. observed values from the model. Uses ggplot2 and model output to display the following. See interpretation below.

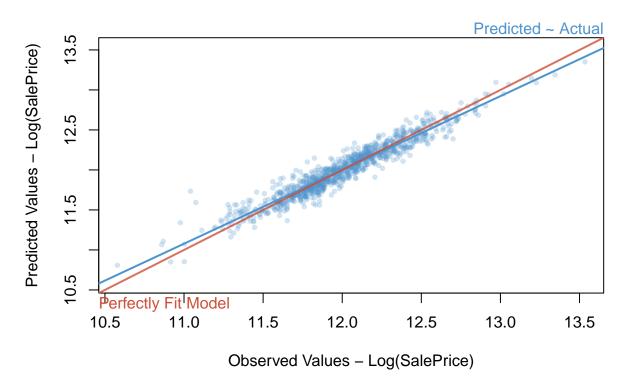

View results of the PCR Model

- See that the variation in the data is very closely resembled actual by changes in independent variables
- Implication? This model fits its own data well, but what is not know if it can predict out of sample data.
- Note that it the data (blue) deviates slightly from perfect line model (red), indicating that the model is slightly skewed from predicted and actual data.

Variation in Predicted vs. Observed Data Model: PCR

PCR Model - Actual (Observed) vs. Predicted

1 (d, ii) - SVR Model

Model Setup

Fit the Model

- Predicted variable: log(SalePrice)
- Dependent variables: non-null factor data (collapsed if over 4 unique values), and all numeric data (pmm imputed if needed). Includes outliers

View and Interpret Results

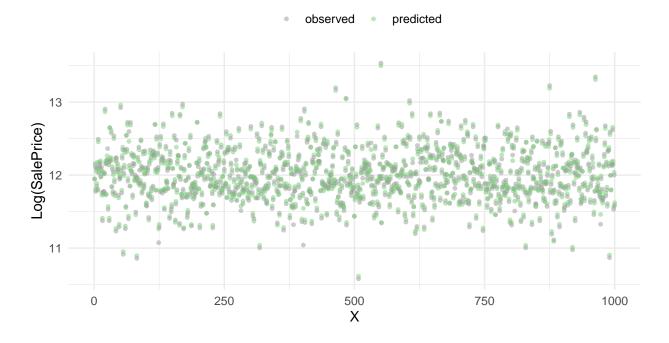

- Note all numbers mentioned below are approximate
- See that the R Squared of the model is around 0.86, and RMSE is 0.14
- See that the model predicts the data well.
- Also, note that the model predicts the data with less error than the linear model. See this from the RMSE or scatter plot of predicted values.

```
# Final model?
fit.svm$finalModel
```

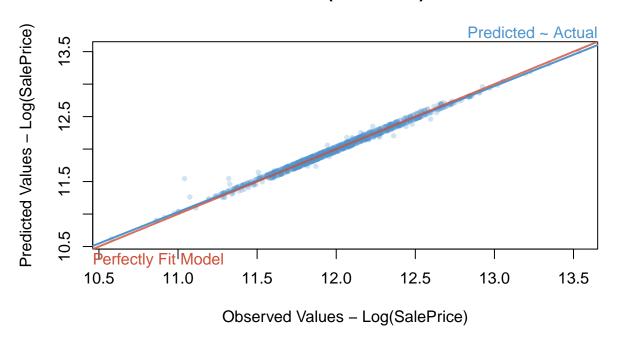

```

Variation in Predicted vs. Observed Data

Model: SVM

SVM Model – Actual (Observed) vs. Predicted

1 (d, iii) - MARS Model

Fit the Model

- Predicted variable: log(SalePrice)
- Dependent variables: non-null factor data (collapsed if over 4 unique values), and all numeric data (pmm imputed if needed). Includes outliers

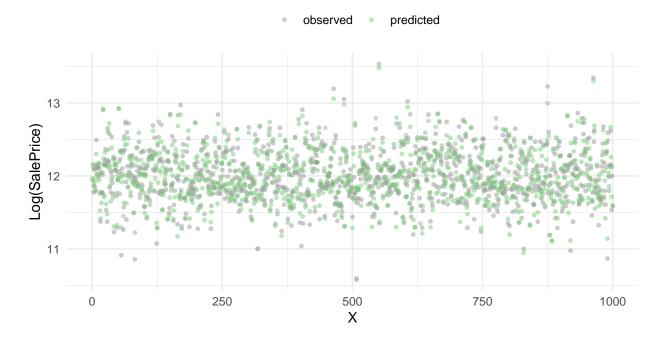

Model Notes		Hyperparameters	RMSE Rsquare	
MARS	caret and earth	Degree = 1, $nprune = 17$	0.1074977	0.9125544

View and Interpret Results

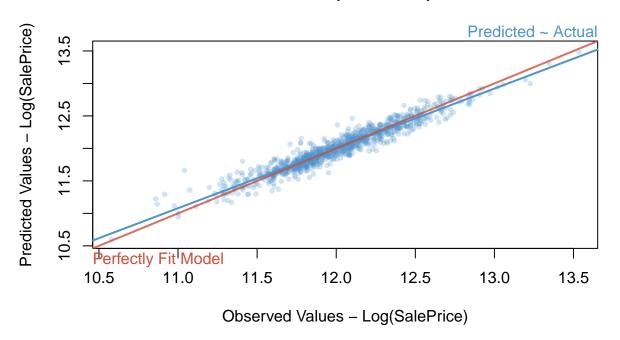

- See that the model overall performs very well, and in fact performs similarly to the PCR model (in terms of RMSE and Adjusted R Squared).
- Again, unsure if the model would do well for prediction of out of sample data, but fits this data extremely well.

```
# Final model?
fit.mars$finalModel
## Selected 17 of 21 terms, and 10 of 94 predictors (nprune=17)
## Termination condition: RSq changed by less than 0.001 at 21 terms
